PROCEDURE	OUTSIDE OF RANGE	WITHIN RANGE RESULTS	REFERENCE RANGE	UNITS
HIV-1 DNA, by PCR		Positive	Detected	FTN
Chlamydia, by PCR		Negative	Negative	
Gonorrhea, by PCR		Negative	Negative	

Human immunodeficiency virus, type 1 (HIV-1) proviral DNA is a qualitative DNA probe that utilizes a nucleic acid amplification technique called Polymerase Chain Reaction (PCR) and nucleic acid hybridization for the detection of HIV-1 DNA in leukocyte preparations. PCR HIV-1 detection has been shown to demonstrate the presence of the virus prior to seroconversion (development of antibody response). This test also has the potential to detect HIV-1 DNA in patients where antibody tests may be ineffective, such as infants born to HIV-1 seropositive mothers or individuals with impaired humoral response (e.g. agammaglobulinemia). This test has not been approved by the U.S. FDA for in-vitro diagnostic testing.
